

Angular Fundamentals

.NET

Angular is an application design framework and development platform for creating efficient and sophisticated single-page applications.

TS/Angular Workspace SetUp

https://angular.io/guide/setup-local

https://code.visualstudio.com/docs/typescript/typescript-compiling

https://angular.io/tutorial/toh-pt0#create-a-new-workspace-and-an-initial-application

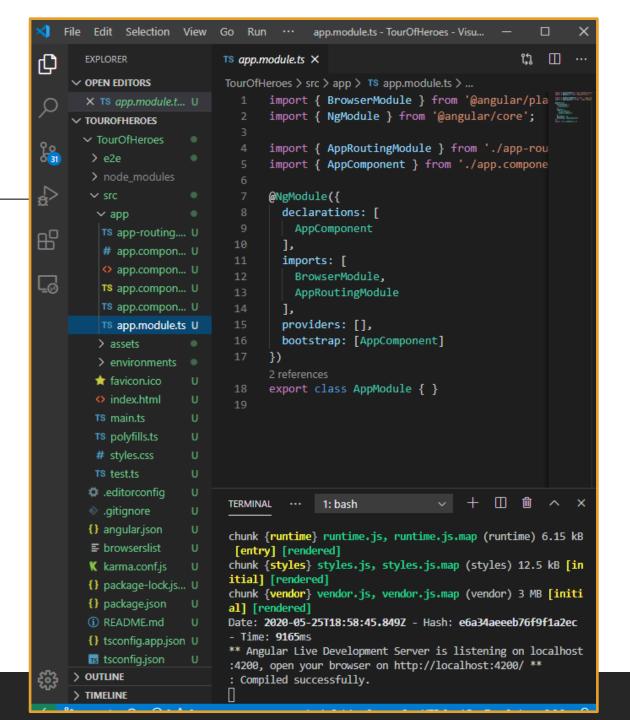

Following the steps from here to create your first Angular App.

- 1. Make sure you have Node.js with node -v in Command Line. If not, go to nodejs.org to get it.
- 2. Install Angular CLI globally with: npm install -g @angular/cli
- 3. Create a *WorkSpace* (accept all the default settings) for your app and install the default starter app with: ng new <my-app-name>
- 4. App name must start with a letter and only contain numbers, letters, and dashes.
- 5. Install the Angular *npm* packages needed with: ng new
- 6. Navigate in the CLI to your app folder with: cd <my-app-name>
- 7. Launch the server and open the browser with the default sample project with: ng serve –open (2 dashes)
- 8. In VS Code, you can install the *Angular Extension Pack* to get additional useful tools.
- 9. VS Code extensions recommendations: <u>C#</u>, <u>C# Extensions</u>, <u>Bracket Pair Colorizer 2</u>, <u>Nuget Gallery</u>, <u>Material Icon Theme</u>,
- 10. Use this <u>Angular Cheat Sheet</u> for quick reference!

Angular WorkSpace

https://angular.io/tutorial/toh-pt0#set-up-your-environment

A workspace contains all the files for one or more projects. A project is the set of files that comprise an app, a library, or end-to-end (e2e) tests.

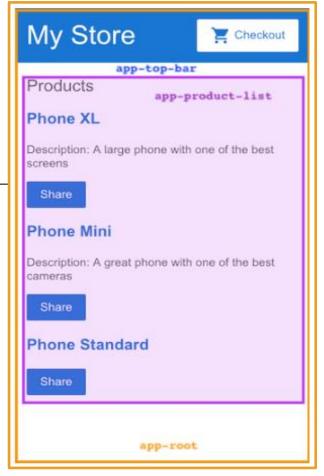

Angular Component

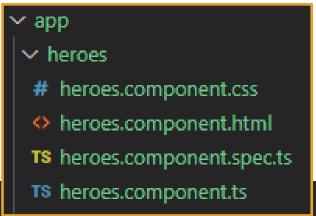

https://angular.io/tutorial/toh-pt0#set-up-your-environment https://angular.io/guide/component-interaction

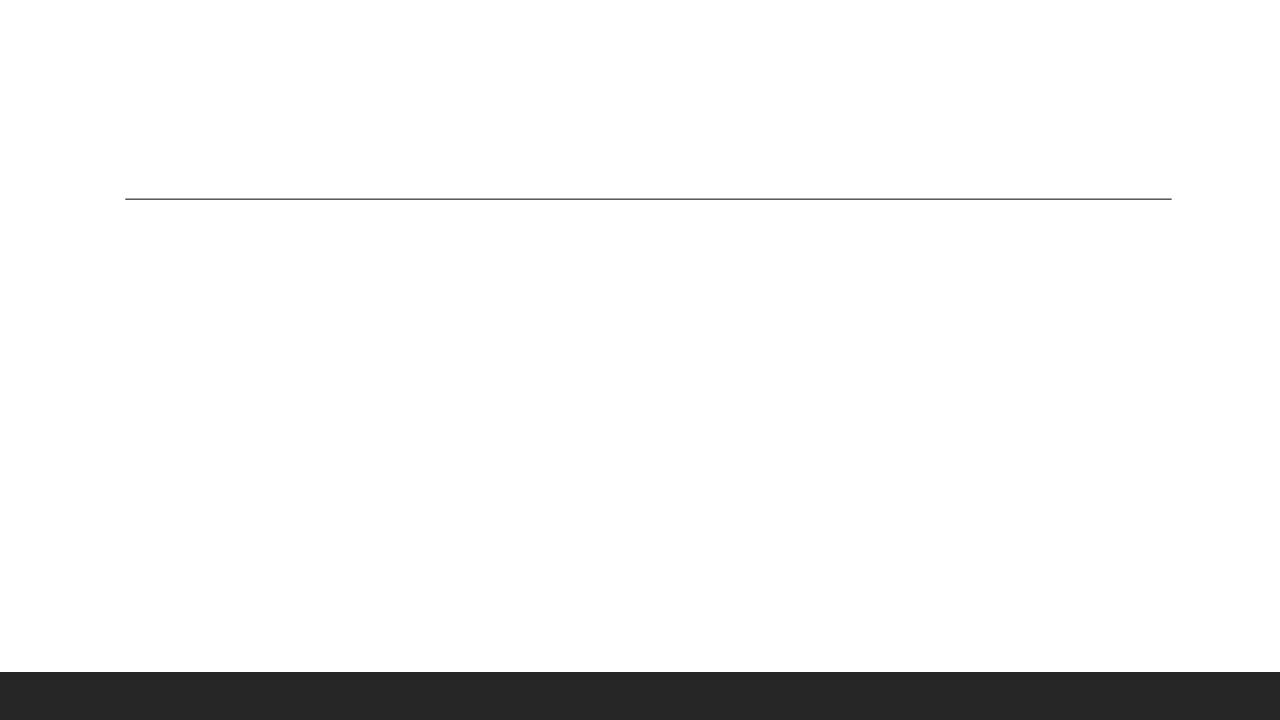

Components are the fundamental building blocks of **Angular** applications. They display data on the screen, listen for user input, and act based on that input.

An *Angular* application comprises a tree of *components*. Each *Angular component* has a specific purpose and responsibility. In the example to the right, there are 3 components displayed:

- *app-root* (orange box) is the application shell. This is the first component to load and the parent of all other components. You can think of it as the base page.
- app-top-bar (blue banner) is the store name and checkout button.
- app-product-list (purple box) is the product list.

Angular Component

https://angular.io/tutorial/toh-pt1#create-the-heroes-component

Use either the Angular helper (R-click the app folder) or the command ng generate component [name] to create a new *component*. The *CLI* creates a new folder for each *component* and generates a .css, .ts, and .html, inside it.

Always import { Component, Onlnit } from @angular/core; library.

Annotate the *component class* with @Component(). @Component is a *decorator* function that specifies the Angular metadata for the *component*:

- 1. The selector name to use for CSS and if importing this component into a .html page.
- 2. The relative .html location.
- 3. The relative .css location.

Use export to make the class available for import by other components.

ngOnInit() is a *lifecycle hook*. It's the best place for @Component initialization logic, such as getting current data from a *Service* or initializing variables.

```
import { Component, OnInit } from '@angular/core';
@Component({
  selector: 'app-heroes',
  templateUrl: './heroes.component.html'
  styleUrls: ['./heroes.component.css']
7 references
export class HeroesComponent implements OnInit {
  0 references
                      app
 constructor() { }
                        heroes
  2 references
                         # heroes.component.css
  ngOnInit(): void {
                         heroes.component.html
                         TS heroes.component.spec.ts
                         TS heroes.component.ts
```

Connect a new Component

https://angular.io/tutorial/toh-pt1#show-the-heroescomponent-view

Every **component** must be declared in **@NgModule** to function.

Angular CLI automatically imports the new component into app.module.ts and declares it under the

@NgModule.declarations array.

```
import { BrowserModule } from '@angular/platform-browser';
import { NgModule } from '@angular/core';
import { FormsModule } from '@angular/forms'; // <-- NgModel lives here
import { AppComponent } from './app.component';
import { HeroesComponent } from './heroes/heroes.component';
@NgModule({
 declarations: [
   AppComponent,
   HeroesComponent
  imports: [
   BrowserModule,
   FormsModule
  providers: [],
  bootstrap: [AppComponent]
export class AppModule { }
```

Angular Interface

https://angular.io/tutorial/toh-pt1#create-a-hero-interface

Interfaces are useful for when you want to define a class or object (with its types), then import it into components where needed.

Create an *interface* with ng generate interface < Component Name > .

Then import that interface into the Component in which you want to use it from the relative file location.

```
src/app/hero.ts

export interface Hero {
  id: number;
   name: string;
}
```

```
import { Component, OnInit } from '@angular/core';
import { Hero } from '../hero';
```

TypeScript Modules

https://www.typescriptlang.org/docs/handbook/modules.html

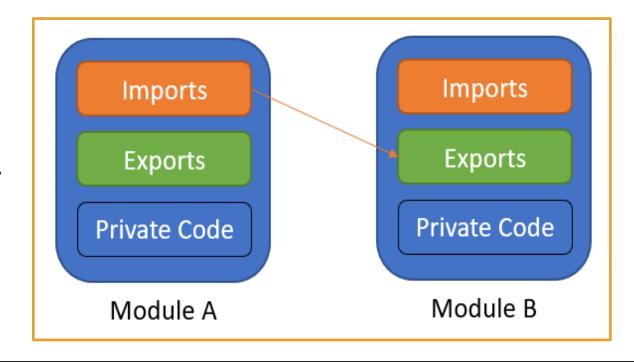

TS shares the JS concept of *Modules*. *Modules* in TS have their own scope. A module must be explicitly exported to make its members visible.

To consume a property **exported** from a different **module**, it must be **imported** using an **import** method.

The relationships between *modules* are specified in terms of *imports* and *exports* at the file level.

In *TS*, any file containing a top-level *import* or *export* is considered a *module*.

A file without any top-level *import* or *export* declarations is treated as a script whose contents are available in the global scope (and therefore in *modules* as well).

TypeScript - Exporting a Declaration

https://www.typescriptlang.org/docs/handbook/modules.html#export

Any declaration (variable, function, class, type alias, interface) can be **exported**.

- 1. Use the **export** keyword to make a class, function, or variable available to other **modules** from within the **module** (**component**).
- Import the class, function, or variable into the module (component) where you want to implement it.

```
export interface StringValidator {
   isAcceptable(s: string): boolean;
}
```

```
import { StringValidator } from "./StringValidator";
export const numberRegexp = /^[0-9]+$/;
export class ZipCodeValidator implements StringValidator {
  isAcceptable(s: string) {
    return s.length === 5 && numberRegexp.test(s);
  }
}
```

Dependency Injection – Services and Injectables

https://angular.io/guide/glossary#dependency-injection-dihttps://angular.io/guide/dependency-injection

Components should always delegate data access to a **Service**. A **Service** can get data from an API web service, local storage, or a mock data source, etc.

Services are integral to Angular. A **service** is an instance of a class that you can make available to any part of your application using **Angular**'s **Dependency Injection** system.

A **Service** is your portal to persist data and have methods to access that data.

The @Injectable() decorator accepts a metadata object for the service, the same way the @Component() decorator does for component classes.

```
import { Injectable } from
import { Hero } from './hero
import { HEROES } from './m
@Injectable({
  providedIn: 'root'
3 references
export class HeroService {
  0 references
  getHeroes(): Hero[] {
    return HEROES;
  0 references
```

Dependency Injection – Services and Injectables

https://angular.io/tutorial/toh-pt4#provide-the-heroservice

https://angular.io/guide/dependency-injection https://angular.io/guide/architecture-services

Services must be registered with Angular's Dependency Injection system before they can be injected into a *Component*.

By default, the *Angular CLI* command ng generate service registers a *provider* with the *root* injector for your *Service* by including *provider* metadata that's providedIn: 'root' in the @Injectable() *decorator* of the *Service Component*.

When a **Service** is provided at the root level, Angular creates a single, shared instance of the **Service** and injects it into any class that <u>asks</u> for it.

Angular will also remove any unused Services.

```
import { Injectable } from
import { Hero } from './hero
import { HEROES } from './m
@Injectable({
  providedIn: 'root'
3 references
export class HeroService {
  0 references
  getHeroes(): Hero[] {
    return HEROES;
  0 references
```

Angular – Use DI to Get a Service

https://angular.io/tutorial/toh-pt4

To create a service to access your stored data,

- 1. Create a Service:
 - ng generate service <serviceName>.
- 2. Import the *Injectable* symbol into the *Service Component*To allow the *Service* to be injected into *Components*:
 - import { Injectable } from '@angular/core';
- Import the Service into the Component where it will be used:
 - import { ServiceName } from '../relative.location';.
- 4. Inject the **Service** into the constructor of the **Component** where it will be used:
 - constructor(private ServiceVariableName: ServiceName) {}.

Use ngOnInit() to access and retrieve data from a service on instantiation of the *Component* instead of using the constructor.

```
import { Hero } from '../hero';
import { HeroService } from '../hero.service';
```

```
0 references | 1 reference
  constructor(private heroService: HeroService) {}

1 reference
  getHeroes(): void {
    this.heroes = this.heroService.getHeroes();
  }
  6 references
  ngOnInit(): void {
    this.getHeroes();
  }
```

How to stop a running Angular Program

https://anthonygiretti.com/2018/03/26/how-to-avoid-port-4200-is-already-in-use-error-with-angular-cli/

- 1. In Command Line, use netstat -ano | findstr:yourPortNumber. (Usually it's 4200 with Angular.) to get your process number (PID). It's on the right or 'Listening'
- 2. In Command Line, use tskill [yourPID#].
- 3. In Command Line, use ng serve -open to recompile and reopen your app.
